

An Electronic Information Item Selection for Trade and  
Traded Item Control Delivery System

## FIELD OF THE INVENTION

The field of this invention relates to an electronic information item selection for trade and the traded item control delivery system, more particularly, it relates to a system that selects, maps, groups, packages, labels and prices media/television information items by time and content. The system includes classifying, indexing, listing, searching and purchasing; as well as a control system for subscriber's secret key issuance, submission, ~~and~~ authorization, and management of the secret key; encryption of the content for transmission, and decryption of the content for delivery and display.

## BACKGROUND OF THE INVENTION

U.S. Pat. Nos. 6,028,599 and 6,341,195 described an electronic program guide and its data base system; U.S. Pat. No. 6,088,722 describes a personalized TV program selection system. Although these patents relate to an electronic program guide and program selection systems, the purpose of those system are all for watching pre-selected and recorded program at later time, while never touch the subject of the present invention. U.S. Pat. No. 6,058,417 describes a subscriber to subscriber electronic trading system on the internet, and U.S. Pat. No. 6,226,675 described a corporate group to corporate group electronic online trading system. These systems are all set up for conventional physical goods trading, there is not yet a real or delayed or relayed time trading system for trading electronic information items, such as TV programs, media, and information products.

Currently, electronic information (such as TV programs) items are provided by information content providers to information content network operators, who assemble the information content by channels and sell to subscribers on a monthly subscription basis. A content provider can sell its own content to many content network operators; a content network operator can have its own mass subscriber base in a region, but content providers in most cases do not have a real time supply relationship with the subscribers associated with a content network; due to limitation of territory, and only provide monthly service to its subscribers within its own network area. Subscribers who pay the monthly subscription fee are provided with the subscribed content (such as TV programs) which is typically

composed of several hundred channels, and in certain time frames (such as several days or certain day) the subscriber may only use a portion of the ~~few~~ content (such as only watch several or tens of channels), the content for the rest of the time (or rest of channels) are wasted. In other cases, due to the internet technology development, if a content provider provides content directly to world wide subscribers via internet by the method of streaming SVOD (Subscription Video on Demand), though the quality is still in question, it breaks the area limitation of regional network's operation and some even bypass the network operation. Similarly, a satellite direct broadcast network operator is not restricted by terrestrial limitations. Both SVOD providers and satellite direct broadcast network operators all encounter the limitation of various nations' government administration policy and media import and export control as well as content usage when their content is delivered to these controlled areas. Since one subscriber can only use one or several channels of media at time, while they owns the access right to the content operator's authorized media pool, which may contains hundreds or thousands of titles or channels of information or media. When the subscriber only uses certain number of titles or channels of media in certain time, the rest of the title or media within or beyond the specified time shall be idle or wasted.

## SUMMARY OF THE INVENTION

The objective of this invention is to provide a trading system that will enable trading of electronic information items (i.e. media/television electronic information items commonly referred to as content). The trading system provides electronic information content providers and network operators with the ability to trade their content via their subscribers. The content providers and network operators who desire to trade their content may be in the same area or different areas and will have the ability to trade their ~~its~~ content in real, delayed, or relayed time. This can be accomplished with content providers in other areas via their corresponding electronic information content network operators in their respective areas or directly through a trading network exchange server and deliver the content in a secured manner. To realize the objective, the invention provides a system for trading electronic information items. The system includes a process for selecting electronic information items for trade, transforming the for trade electronic information items into trading packages or dealpacks, and controlling delivery of the dealpacks. In one preferred embodiment, the system includes a control device, such as client side TV set-top box, a computer, a handheld PC, PDA, server side cable head-end, telecom node, or computer hub, on which an electronic program item selection software means can be downloaded/upgraded. The software means for selecting electronic program items conducts the selection of the electronic information items by their specified time frame and content. The packaging process or system (can be called the pack-engine) then maps and groups the remaining (for trade) items in accordance with a pre-defined grid/matrix into trading packages or dealpacks. Label data and price information are incorporated into the trading packages or dealpacks by the packaging process. The dealpacks are listed for trade (which may occur in, delayed, relayed time). The system includes a trading network center

for controlling dealpack indexing, listing, searching, trading, charging and billing as well their encryption for transmission and decryption for delivery and display.

The above software means for selection of electronic information items (such as TV programs) includes an interactive electronic program selection guide (EPG). Such a selection guide could be interactively operated via a control device, such as set-top box, a computer, and/or handheld device, that includes a rolling display of the listing/guide on TV/PC or via internet web pages directly or through internet channel. A user makes a selection via the selection guide (such as EPG), which may include the time frame or time frame group, or item (such as program channel/title or channel/title combination), which are listed by pre-defined format. When selecting items, a user can press keys on a pad (such as computer or phone), buttons on a control unit (such as a remote control, a mouse, or a touch panel), or use touch pen to select some items as for-use and others for trade (where they may be rented, leased, or sold, etc.) in a specified time frame. Also a user can select to further display some label information (such as program briefing, author, publishing date etc.). Once determined, the items for trade shall be immediately mapped into a pre-defined grid/matrix for regrouping and pricing by the pack-engine on the server side, where they are then put into trading status. The pack-engine is a packaging process or system that transforms the content in the dealpacks as seen in Fig.1. This status shall be the authorization from the user to their content/network operator to send those for trade items into a regional trading database server, which is linked with the trading database exchange server and updated in real time to enable internal (trading among the content/network operator's own subscribers) or external (trading with subscribers of other networks) trading.

The trading system includes regional log-on servers which are linked with the trading exchange server. The regional servers provide localized web interface for log-on by the local network operator and its subscribers and provide a classified listing area (such as on the internet or cable network) for the dealpacks. They also allow searching, selection, and purchase of the dealpacks which can be accomplished by key words, class, and operators names for registered log-on local or related other regions' subscribers. The trading system operator is in charge of the administration and operation of the trading database and servers, including registering content/network operators and their subscribers, providing log-on authorization, online search system maintenance, trading settlement, secret key issuance/release, and management of the drop-in subscribers' control device (such as set-top box or network card), sales and their log-on authorization. Once the content network operator has registered its subscribers on the trading network, they can then link to the time-tagged for trade trading dealpack database server to the trading exchange servers for listing out. The operator's subscribers and drop-in users can then search the listed dealpacks and make purchases. For one preferred embodiment of the invention, the search results could be a list and include the price of the dealpacks. If a user clicks on a certain dealpack, it can further display its labeling data, such as program titles, authors, directors, main actor/actress, brief description of the program, publishing dates,

pictures, previews and time for play, etc. Once purchased, the trading center can use debt (where they may settle the account with the operators monthly), or use a credit card/bank card as payment tool to close deal online. Once paid, the purchaser shall be given a secret key, which could be administered by the trading center on behalf of the purchaser to deliver the dealpack to the purchaser by scheduled time, or the secret key could be submitted by the purchaser him/herself via internet, cable or wirelessly to activate the dealpack delivery and display of its content.

The secret key for each dealpack is generated by an algorithm of assembling the selling-subscriber's key, time frame identifier and identifier of the dealpack as well as verifier of payment for the dealpack.

The control devices may be a set-top box type device, remote handheld PC, PDA, server side cable head-end, telecom node, or computer hub. The control device operates together with the trading network's subscriber administration, network administration and billing system to provide the purchased dealpack encryption and decryption chain and delivery conduit to the purchaser. The method includes the steps of: downloading the EPG software means; selecting items for-use and confirming the items for trade; send the items for trade to the pack-engine for packaging, pricing and sending out to trading exchange server via the database server for listing. The purchaser searches through the listed dealpacks and purchases the secret key for the dealpacks they select. The network administrator controls and authenticates the secret key, encrypts and transmits the dealpack. Subscribers on the same network trade with each other via the network center to verify the secret key and issue a pass to let control devices, such as a set-top box or a network card release and deliver the dealpack; while subscribers on different network trade each other via network center/gateway and set-top box together to verify the secret key and issue a pass to deliver the dealpack.

The objective and characteristics of the invention will become apparent from the following drawings and the detailed description.

## BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is the overall flow chart of the information item selection and packaging into dealpack for listing on the trading network.

FIG. 2 is the overall block diagram of dealpack trading and delivery system.

FIG. 3 is the process block diagram of the dealpack search, selection, purchase and receiving by a user of the trading system.

FIG. 4 is the block diagram of dealpack secret key assembling and generating method

## DETAILED DESCRIPTION

A preferred embodiment of the present invention is disclosed in the flow chart/block diagram as illustrated in FIG. 1. A user first selects the program they wanted to watch. They can start from a classification index 100a, use hand held control unit to select the items for-use 111, then they select from the EPG 100 the wanted channels 110 and its code or name 130. If they want to further understand the program, the subscriber can select the program 131, then a window 132 will open and it illustrates related information about the program. The subscriber can further select the time frame 188 based on the selected channel combination 140, including to input/select the starting time and date 151 and ending time and date 152, then confirm with 160. Once confirmed, under the account number 171 of the subscriber, the packaging system or pack-engine 180PE will put all the rest (i.e. the remaining) of the channels/programs 170 into a pre-defined grid/matrix 180 for pricing 185 in accordance with the channels 110 and time frame 188 and show time 184 as well as dealpack ID 187, and class code 189. Upon confirmation for trade 186, the dealpacks 187 will be automatically be sent to the trading network database server 190 linking the trading network control center exchange server 200 for listing.

Fig. 2 is an illustration of the trading system where two content/network operators are associated with the trading system through the trading center 200. The trading center includes a listing database and an exchange server. Before dealpack trading can begin, content/network operator A and content/network operator B register and log-on to the trading network center 200. The subscribers associated with these content/network operators are automatically registered on trading network. Fig. 3 shows the steps for purchasing a dealpack which begin with the step where the content/network operators log-on to the trading network (step 300) through dealpack release (step 361). Database servers 190a and 190b are linked with the trading network center 200. The subscribers associated with content/network operators A,B are connected into the trading network center 200 via their operating device. Specifically, subscriber A1 associated with content/network operator A is connected to the trading network center 200 by their computer 211. Subscriber A2 is connected by their TV. Drop in subscriber 1 and drop in subscriber 2 are not associated with either content/network operator. Drop in subscriber 1 is connected to the trading network center by computer 201 and drop in subscriber 2 is connected by TV 202. The trading system supports a variety of different users, some of which have access to content (subscribers a1, a2, b1 and b2 seen in Fig. 2) and those who only have access to content through the trading network center 200 (drop-in user 1 and drop-in user seen in Fig. 2)

It is to be understood that the above preferred embodiment of the invention is only

illustrated the key concept and composition of this invention, many variations and modification can be made based on the accent of the above embodiment, which will be apparent to one skilled in the art, that are also within the spirit and scope of the invention as set forth in the claims below.
